Bioinformation

Gene Symbol	HGFAC
Gene Full Name	HGF activator
Background	This gene encodes a member of the peptidase S1 protein family. The encoded protein is first synthesized as an inactive single-chain precursor before being activated to a heterodimeric form by endoproteolytic processing. It acts as serine protease that converts hepatocyte growth factor to the active form. Alternative splicing results in multiple transcript variants. [provided by RefSeq, Jul 2014]
Function	Activates hepatocyte growth factor (HGF) by converting it from a single chain to a heterodimeric form. [UniProt]
